Abstract: Technology has derived humonous growth in generation of the data and need of Data Warehouse. The performance of business decisions depends upon the optimality of the operations performed on data and design of its Data Ware House (DWH) system. Mostly, DWH system’s design methodologies focus on Extraction, Transformation and Loading (ETL) and related processes. Big Data paradigm is emerging as a big challenge to ETL and causing performance degradation and frequent re-configuration to meet day-to-day operational tasks. Recent research claims on automations of ETL processes have emerged as possible solution in Big Data paradigm. In this proposal, DWH system process is considered as a complete and unified tool which covers all intermediate steps from source data to report generation; for analysis and decision making. This work attempts the automation of source data extraction, transformation & loading and reporting. A cost effective DWH system solution is proposed by avoiding the use of commercial tools without compromising the performance.

Keywords: DWH, Automation, maintainability, ETL, Data Science, Analytics

I. Introduction

Data is the backbone of every decision. A quote by Clive Humby establishes the spirit of statement [1].

“Data is the new oil. It’s valuable, but if unrefined it cannot really be used. It has to be changed into gas, plastic, chemicals, etc. to create a valuable entity that drives profitable activity; so must data be broken down, analyzed for it to have value.”

The soul of this statement is to give a pathway for data scientists to consider data as most valuable asset for every organization. Data exists everywhere, but we need to understand data in holistic view – Why to store? What to store? How to Store? Where to store? What I am getting out of it? Is the results aligned with the organizational goals? When we think about these questions and then start planning for the strategy, it will lead to the excellent results. In fact, why data is stored is really driving argument. Stored data allows to have insight of data and to take the necessary analytics followed by actions which are based on the results. Ever increasing volume of data is not as simple, as it is coming all the way in the forms of structured and unstructured data. Structured data is business data having well defined structure which generally supports “Schema on Write” paradigm. Structured data can easily be stored in the relational database management systems whereas for unstructured data, there is a requirement of many tools and utilities like Hadoop and No-SQL database management systems.

In general, DWH system automation takes input in the form of heterogeneous data from multiple data sources and the output is a unified data which is available at destination source. Destination source may be a database or flat file or any other type of data repository. The resultant data is utilized by different verticals such as decision making, analytical techniques, business intelligence and many more. The resultant output of DWH system is unified data. Use of this data depends upon different business unit requirements. DWH system is implemented if and only if the unified data is available at production fact tables. Beyond this stage, reporting/retrieval is considered as the next phase after DWH system development. To achieve the DWH system automation, ETL job automation and workflow optimizations are considered and implemented.

Big data is an emerging field and interchangeably used with heavy data sets. The definition says “Big data is a collection of large or complex data sets that cannot be processed by traditional data processing applications and tools”. DWH is a term used to describe container where data is stored. Relational database management systems are used for storing structured data. A recently evolved framework like Hadoop is used to store large data sets using distributed processing by utilizing programming models. The term Big Data is frequently associated with unstructured data. Data analytics acts on top of the DWH for decision making. Both relational DWH system and big data based DWH system has unique properties of their own. Relational DWH system can only handle structured data whereas big data based DWH system can handle unstructured and semi-structured data. In fact both DWH systems (Relational and Big Data) should work in tandem with each other so as to get the decision metrics. Although there is a lot of hype about big data and its usage, but still there is a need to discuss it. Nearly 80% of the data is...
unstructured and is like raw crude oil, but the importance of the relational data (structured data) cannot be ignored.

Data must be refined and stored for further processing. Data elements from different sources can merged in the data for final product. The final product facilitates organization in decision making for improved productivity.

ETL converts data into useful and desired forms. ETL process is a sub process to design the DWH system and can be performed with either commercial tools or by customized programming at OS and database levels.

Post ETL operations, data is available in DWH and meaningful information can be retrieved from it by using some metric based logical reporting. Reporting is considered an additional area, over and above DWH system and ETL, and is a key factor towards decision making process. An efficient and in-time reporting serves its purpose for improved profitability of any organization. Therefore, it should be dealt with care and importance. The reporting from DWH should be well in-line with the date in system. When it comes to the large data sets, data processing in DWH system goes on as ongoing activity; heavy and un-optimized reporting mechanism can have a severe impact on DWH.

Researchers have put in their efforts to build a system, integrate the processes and to have a view of DWH systems [1][2]. The problem has been taken as big data problem and various tools have been deployed for the solution. Many researchers have put in their efforts in the field of DWH development and its processes by their own ontologies.

It has been observed that, the whole process of DWH including reporting has never been viewed as a unified tool which can take an input and give output in the most desired forms. All sub-processes should be aligned and well integrated so that it requires minimum manual intervention. The business user/technical users of the framework need not necessarily know the internal technical details of the system and can focus on the business results. There is a need of relational DWH framework, which is completely automated in nature from source data extraction, transformation, loading until optimized reporting. Data retrieval refers to extracting data from DWH as per business requirement. The whole process can be easily achieved using various commercial utilities and tools which need heavy investment and license costs.

In this research paper, we have provided an automated framework to set up the relational DWH system for organization of any size without the use of commercial tools and utilities. The implementation can be done in any programming language of programmer’s choice with knowledge of database systems. The complete automated DWH is categorized in mainly three parts – automation of source data extraction, data transformation and loading, data retrieval.

Success of a DWH project heavenly depends on smoothness of the processes incorporated in it and post deployment on the day-to-day performance. Not only should the development of DWH system be focused, but also the stability of its operations, process automation and tuning. This is a continuous activity during whole life span of the DWH project.

Setting up a DWH is a tedious task for small and medium scale industries due to cost and complexity involved in maintaining the system. Motivations of this study are to put in place a robust DWH system architecture with complete automation and cost effectiveness with minimum manual intervention for maintenance. In this paper, process automation and maintainability issues are addressed for DWH project without use of commercial tools. Study is oriented towards providing a system that is self-sustainable and self-healing for handling hick-ups during data processing. A Self-sustainable system is a system where minimal manual intervention is required and self-healing system refers to a system where majority of abnormality during operations are handled by the system itself. These properties are key ingredients for automating the system.

This research is providing a framework to setup a cost effective and automated DWH system without using commercial tools. The proposed framework considers the “reporting” as an integral eternal process of DWH building, which is lacking in existing studies. A unified approach which handles the intermediate steps is an outcome of this research with improved performance at optimized cost. Performance of framework has been evaluated for improved metrics. The framework aims to target organizations looking for setup its DWH system at minimum cost and at optimized performance.

Remainder paper is organized as follows: Section II reviews a wide range of related works in the realm of DWH system for automation. Section III describes the problem definition. In section IV, proposed approach, methods and materials are given respectively. The performance and results are presented in Section V. Finally, Section VI summarizes the conclusions and future directions of this work.

II. Literature Review

NoSQL based DWH system is proposed which contains social networking data. Automated transformation rules are used for transition of conceptual database to NoSQL database. The automated transformation rules are evaluated using TPC-DS benchmark [1]. Document based NoSQL data stores are used for NoSQL based DWH system approach. Agile development approach is utilized to develop DWH system. Cross platform de-normalization technology is harnessed for building DWH system [2]. Big DWH refers to a DWH where complex, huge and variety of data is stored using big data technologies. Hadoop is proposed as alternative for building big DWH system [3]. Massively parallel processing (MPP) system is proposed for building scalable DWH system. MPP database and DWH systems are designed. The MPP enabled DWH system is evaluated using IBM Datastage ETL tool. MPP enabled DWH system is applied in telecommunication domain [4]. With emerging need to process unstructured data, non-relational database management systems (RDBMS) are required. Many legacy and current application uses RDBMS as database and now same applications are expected to handle unstructured data. There is heavy cost involved in replacement of applications to use non-relational database, a mechanism is required for enabling data transformation and keep application compatibility with database. An automated framework is presented for migration RDBMS data to Not only SQL (No-SQL) based database with compatibility of
application with NoSQL database [5]. Data preparation is considered as a processing steps for data including data discovery, data extraction, data profiling, format transformation, source selection, matching, mapping, data repair, duplicate detection and data fusion. Three questions are considered for data preparation automation a) can we automate? b) Should we automate? c) Must we automate? [6]

To achieve automated big data ETL framework, an extendable ETL framework is presented to address issues associated with big data. For big data ETL, user defined function (UDF) component is introduced. UDF component enables ETL developers with reusable algorithmic layout and cost model generates effective ETL workflow execution plan [7]. Continuous or real time automated auditing using audit DW system and data marts is presented. Audit DW and data marts contains near real time records of financial transactions to enable auditors to achieve continuous auditing [8]. Authors have proposed a framework for federation DWH and further proposed algorithms for pre-processing, query decomposition and results [9]. The ultimate aim is to build up a system up and above various DWH systems and called them federation DWH. The group of DWH federation system containing semantic information and users has a unified view for various DWHs. Authors have been able to achieve data generalization and give a prototype of their approach by making an application to use the same.

Proposal has identified DWH problem as big data problem in which data is increasing and focused on speed and number of users [10]. Authors have proposed a new DWH system framework named General Engineering and Manufacturing DWH (GEM-D) in which highly effective data gathering techniques are deployed so as to achieve “just in time” data gathering. To achieve the objectives, authors have proposed a model having source systems, staging layer, logical layer, analysis tools and Business Intelligence (BI) tools and reporting tools.

Researchers have put in their efforts into addressing the issue of designing a data center for tobacco industry. The data center focus on effective data mining and DWH system techniques [11]. The aim is to provide a system specific to DWH and data mining which can facilitate trend analysis and future forecasting. Authors have proposed a framework which is production process control centric to improve the processes based on data mining and DWH system techniques.

A recent work has proposed an improved model for enterprise DWH storage system named, “UStore” [12]. The storage system aimed at problem of data storage around 3 petabytes in China’s bank card enterprise “UnionPay”. The “UStore” framework is having key features of Storage Unification, query efficiency and user transparency. It is based upon single physical table multiple view architecture which facilitate efficient and effective query execution. Ustore helps in handling data redundancy without any changes in existing query logic.

Another work emphasizes on the scalability aspect of big data sets without investing much in the hardware improvements [13]. Boolean queries are mapped to SQL for clinical research DWH system. Custom query generation has been used and compared with default query generation in clinical research DWH system. Authors have compared execution time for SQL queries generated by custom Common Table Expression (CTE) generator and default SQL query generator. Authors have observed significant improvements in results for CTE based scalable solution without costly hardware upgrades.

Peer Review Markup Language (PRML) for education sector DWH system focused on peer assessment [14]. Authors have addressed the difficulties while comparing the functionalities of two different peer review systems supporting different protocols. Authors have put in their efforts to generate a generic data set and then comparing the different peer assessment systems using PRML.

A comparison among different modeling techniques among Kimball data modeling approach, Inmon subject modeling approach and data vault approach for scalability and flexibility analysis was attempted [15]. The quality aspects of DWH system upon context based approach were focused recently [16]. Authors in [17] have tried to address need of small and medium enterprises. A DWH system model that is based on service oriented architecture has been proposed.

Data warehouser is like an artist who can examine DWH schema pictures in detail [18]. Authors have suggested that a good DWHr should have in depth knowledge to implement DWH. Authors have put efforts in the field of higher education by business intelligence framework [19]. Emphasis has to be on extraction, loading and transformation along with data integration to develop and manage higher education centric business intelligence solution. Authors have proposed a DWH system framework aimed at decision support system for Egypt’s tourism sector. The DWH can be used by multiple agencies / entities to decide on their key decisions and help to mitigate the risk [20]. A quality driven DWH system should be objective and keep quality aspect in the center of the ETL processes while building DWH [21]. The quality approach is to look for corrupt data before loading and approach is validated through a case study using Oracle Semantic database source. Particle swarm optimization is focused with respect to swarm intelligence [22]. Basis data mining terminologies are presented with past and ongoing work of swarm intelligence in data mining. Data mining framework is presented for mining weather data [23]. Self-organizing data mining approach called enhanced Group Method of Data Handling (e-GMDH) is presented.

In this paper, we discuss a framework to design an automated DWH system at optimized cost. Although, there are many challenges and issues that DWH system needs to handle, here we only concentrate on issues related to automating DWH system with cost effectiveness. In this context, several parameters need to be considered. The parameters are cost effectiveness, time taken for data processing, self-healing property of system and retrieval time metrics.

To address the cost effective automation problem of DWH system we need to split DWH system into sub processes and work on their automation. First, DWH system is split into three processes for automation and then, automate individual processes. Existing techniques and tools are not specifically tailored to accommodate the need of an automated DWH system without taking help of commercial tools in DWH system development and its reporting. Reporting automation has not been considered as integral part of DWH system.
development process. Summary of existing work is described in Table 1.

Table 1. Summary Table of Existing Work

III. Problem Definition

On reviewing literature in the realms of self-computing and DWH, only a few works have tried to address issues related to automation of DWH system with retrieval mechanism and at the same time maintaining cost effectiveness of overall system. Majority of research is carried out by focusing on ETL and its workflow. ETL is an inevitable sub process of a DWH system but it is not a DWH. It is a combination of many sub systems mainly of extraction, transformation and loading. In
related literature, research is performed to shift paradigm towards fully automated ETL framework. Automation of DWH system can be achieved as a result of sub systems automation and binding of all sub system in seamless manner. Research is carried out to automate migration of RDBMS to NoSQL. Extendable ETL framework is used to achieve automated big data ETL framework. Automated auditing is examined for research by making use of near real time DWH. ETL workflow execution plan is utilized for automation. It is observed that, ETL tools (like IBM Datastage or Informatica) are used frequently for such system’s automation. ETL workflow automation is interchangeably considered as DWH system automation. When ETL tools steps-in during DWH system development, it becomes costly affair due to cost associated with the tools. To manage the cost, NoSQL based databases, big data approach and open source technologies are worked upon with ETL tools. There are some strong points of RDBMS and specific strengths which are associated with NoSQL based databases. Both type of databases have specific purpose and utilities. RDBMS cannot be replaced by NoSQL databases and vice versa but can be used together to achieve specific goals.

End result of DWH is reporting. Reporting and retrieval are used interchangeably. Separate tools are available for ETL and reporting. Sometimes, ETL tools and reporting tools are part of an enterprise business suit. For reporting (which is an ultimate aim for DWH), an organization needs to either procure reporting tool or build in-house reporting application for specific reporting needs. There is a need of integrated DWH system framework which meets reporting requirement from designing stages of the system development process. Data retrieval handles the organization’s specific reporting requirements and DWH is designed in such a way that reporting is quick and just in time.

By keeping in view the thoughts and studies in relevant field, some gaps are identified towards cost effective automated DWH system’s goal which are mentioned as:

a) Not only ETL process automation, but overall DWH system process automation needs to be considered for research.

b) DWH system process should consider reporting/retrieval process as integral part in addition to ETL process.

c) Explore possibilities to develop automated DWH system with inbuilt utilities to avoid commercial ETL and reporting tools.

IV. Proposed Approach: Methods & Materials

DWH consists of three major processes which are:

Data extraction from source, Transformation and Loading. Another term “Retrieval” is added to the DWH development process which contributes to decision making. The processes to automate are identified and are segregated for seamless and efficient automation.

a) Source Data Process Automation,

b) Data Transformation and Loading Automation

c) Data Retrieval Automation.

The sub processes automation is optimized and integration of sub processes is carried out in tightly coupled way for desired output. The individual sub processes automation is explained in following subsections. The flow of sub systems automation is shown in Figure 1.

**Figure 1. Sub Systems Automation Flow**

**Source Data Process Automation:**

DWH data originates from different data sources having heterogeneous technology platforms. ETL processes are involved to build up a DWH. Extraction means extract data from different sources and give it as feed to transformation engine. In this section, we focus at automating the whole process of data extraction using various tools and utilities. We propose a mediation system, which interacts with various data sources having data in different formats like hexadecimal formats, binary format or any other device specific formats. The mediation system is a dedicated system having specialization in handling incoming data streams and subsequently converts it into desirable format and can output the multiple streams to different staging locations in parallel. Error handling has been incorporated as an integral part of mediation system which detects logical expression and data quality issues in incoming data streams. Erroneous data is identified and reprocessed to ensure complete data integrity for staging area. Filtering logic is implemented to obtain selective data at staging area and eliminating other data. The parsers are integral part of the mediation system which converts data into desirable format. The required data streams generated from mediation system are fed into staging area at specific locations in raw format so that they may be available for transformation and further for loading. The process becomes automated using parsers in mediation system which can be coded in C language on Unix/Linux platform. The mediation system is getting continuous data streams from various sources and parsers are processing data streams to the configurable data formats. The data is pushed (still raw data in view of DWH) to the staging area for further processing.

The raw data is available at staging area for further processing. Source data process automation is shown in figure 2.

**Data Transformation and Loading Automation:**

Raw data is automatically pushed towards staging area by mediation system. The data is available at predefined directory locations of staging area. Our target is to transform raw data to desired format and make it available for loading. Data transformation and loading automation refers to continuous flow of incoming data from different sources so that transformation take place on the fly. Proposed approach is to get data streams from different data sources at staging server in the form of physical files using OS storage. At the same time, the data available at Operating System (OS) storage is viewed in the form of table by making use of external table concept. Loading engine fetches transformed data from staging area and load it into the fact area. The automation is achieved in such a way that it supports large volume of data arriving at high velocity. Data transformation logic is written using external table and using view functionality for transformation so that as and when data arrives in the files at
An Approach for Implementation of Cost Effective Automated Data Warehouse System

OS level, it would be auto transformed on the basis of logic defined in the view on external table.

![Source Data Process Automation Diagram](image)

**Figure 2. Source Data Process Automation**

By doing so, data is automatically available in the form of tables as and when data arrived at staging area in the form of flat files.

**Data Retrieval Automation:**
In data retrieval automation, various functions have been proposed including:
- **Function parallel_thread** which sets the maximum threshold for reporting to manage load on DWH database.
- **Function select_list** checks for the report requirement conditions and accordingly logic is built to get desired result from the DWH.
- **Function request_processing** define report location at DWH server and execute optimize SQL generated on the basis of logic in previous function. Required report results are streamed to the specified location.
- **Function system_clear** checks for the storage capacity and delete obsolete data based on pre-specified conditions.
- **Function report_submission** updates the incoming request status and check for maximum threads to execute or put in queue depends upon current running reporting threads. Required data location is identified precisely and query aimed at the only partition where data is expected. Structured query language is generated and finally, highly tuned SQL executed for report data.
The output of the experiment has improved the data process automation framework that facilitates highly tuned data processing for large data volumes. Data Transformation and Loading automation framework is shown in figure 3. As detailed in figure 3, data files are available at staging serve in step 1. In step 2 of figure 3, group of files are identified which is referred as bunch. In step 3, there are many bunches of files placed at predefined database directory which points to a physical directory at operating system. In step 4, data available in form of flat files at database directory is reflected as tabular. The tables are called as external table. In step 5, the data available in external tables is transformed by using the database view functionality. Transformed data from database view is copied to temporary table which is exact clone of final (fact) table as shown in step 6. In step 7 the temporary table is exchanged with final (fact) table using partitioned exchange technique. The process is repeated for the remaining bunches.

Let us understand Data Transformation and Loading Automation as a dataflow description with the help of a use case of telecom Call Data Record (CDR) DWH. At this stage, raw data files in CSV format is available at respective predefined destination of staging server as shown in step 1. Related CSV files of a particular region is grouped which can be referred as bunch of files as shown in step 2 of figure 3. The bunch of CSV files (still raw data) passes to database directory, which in turn refers to the physical location on the staging server as shown in step 3. Now raw data containing CDR of customer is available in external table as is form as shown in step 4. Data base view has configured on external table, which perform task of transformation including converting raw string to desired date format, converting text to numbers, performs join operation and many others. Raw data transformation has achieved through this stage as shown in step 5. Data loading starts using transformed data from view (referring external table) to temporary table, which is the same as destination (fact) table. The activity has shown in step 6. Temporary table is sandwiched between fact tables using partition exchange mechanism and is shown in step 7. Now, fact table of step 7 is having the processed CDR of telecom subscriber, which can be utilize for reporting, billing, analytics and other business activities. Automation process viewed as unified tool is as shown in figure 4.

Figure 3. Data Transformation and Loading Automation

![Figure 3: Data Transformation and Loading Automation](image)

Figure 4. Automation as Unified Tool

Major verticals for DWH system of an organization is ETL and we have added additional dimension to it which is “retrieval”. A DWH system without retrieval techniques is of no use and retrieval should be planned and taken as the integrated component for building DWH system. Post individual process automation, the processes are tailored in a highly cohesive manner through programming technology platform such that every data unit moves from one process to other in highly efficient manner and produces the desired output. The integrated process automation framework resulted in an improved DWH system automation model which takes cares of the reporting paradigm also.

During model development, it has been observed that when flow of data is high, in the form of data stream/files, data extraction has becomes a vital task to handle and its automation handling involved many complex sub tasks. Automation should take care of the error handling and self-reviving (system recovery) techniques and optimization and logging so that system overhead for next sub process can be minimized. The automation framework without use of
commercial tools needs careful attention for transformation, loading and retrieval too.

**Advantage of using this framework:**
- Improvise end to end automation framework
- Retrieval is considered as core component of a DWH system.
- All subsystems of DWH including retrieval are integrated and automated to view as black box.
- Low cost solution without use of commercial tools
- Highly customizable and improved performance.

It has been presented as a complete automated framework which binds sub processes into cohesive way.

**V. Performance and Results**

The results of the experiment are automation of sub frameworks that majorly contributes to build a DWH system. In addition to the existing sub-processes, retrieval has been identified as an integral part for a successful DWH system and retrieval sub process has been improvised for automation. The results are as discussed below:

- **Source data process automation**: The automated resultant framework for source data process automation has mediation system in place which has inbuilt utility for error detection and correction mechanism. The data streams of raw data coming from various sources have been collected at the receiving end of the mediation system. Only selective data after filtering the raw data and its refinement has been sent further to the output data streams at different locations of the staging servers. Its duty of the mediation system to control the flow of incoming data and to ensure that the number of data streams received should be sent to the desired locations at staging server. In case of any issues like network crunch or transfer fail, mediation system ensures to resend the correct data. The result of the sub process automation is smooth flow of data from source system, its filtering and refinement, buffer control and send to the desired staging locations for further processing.

- **Data Transformation and Loading Automation**: The optimized automation framework has used number of technologies in auto-switch mode to process the data towards desired tables for reporting. Raw data has been configured in the form of external tables based on the logic. The transformation logic has been written logically on external tables and switching of the raw files and further loading to the tables in iterative way such that data flow from raw files to the fact tables has been performed in a fine way. The process is iterative in nature and keeps on loading data and file switching has been performed in highly efficient way so that no manual intervention is required.

- **Data Retrieval Automation**: The retrieval process automation is to automate the most crucial part i.e. reporting part based on DWH. The framework resulted in the data request raised by any interface to be handled in a way that framework has described. The data request in desired format has been updated in a meta-data table and the request parameters have been stored. The parameters may consist of filter conditions and other indicative constraints for a report. The parameters are stored in the variables and number of requests have been checked whether they are permissible or not with number of parallel threads. The optimized logic has been identified for the report and tuning parameters have been incorporated. The request has been submitted in queued way and the request is executed and report is stored at desired location.

**A. Observations about the results (compare / contrast between experiments)**

Metrics are identified to evaluate the proposal. The research concentrates at reducing cost of overall DWH system process automation. Therefore, cost effectiveness is taken as one metrics to evaluate the result. The automated framework should ensure efficient data processing without compromising performance. Therefore, time taken for data processing is considered as a metrics for result evaluation. During automation, system should avoid manual intervention in most of the cases. Therefore, self-healing property of system is considered for evaluation. Reporting is considered as integral part during DWH system automation. Retrieval/reporting time metrics is considered for result evaluation.

Therefore, results are evaluated on the following parameters:
- Cost Effectiveness
- Time taken for data processing
- Self-healing property of system.
- Retrieval time metrics.

The resulted output has shown an obvious movement of the data streams that not only facilitates automated flow but use of commercial ETL tools has been eliminated. Error detection and correction mechanism have been incorporated at every sub-processes of the framework to ensure self-healing property of the model. The results have been evaluated to automate the entire process and keeping the above mentioned parameters in consideration to compare the results for optimization/improvement. Observations about the results on parameters are discussed in below sections.

1) **Cost Effectiveness**

The resultant framework has not used any commercial tools and is based on customized blend of technology mix. The sub processes of the model can be implemented for DWH system automation by making use of programming skills of the developer with database conceptual knowledge. The model is
highly cost effective and can be easily integrate(d) with DBMS software (open source as well) that gives facility of external table and partitioning concept. It’s been found that at any of the sub processes, no commercial tool has been used and framework supports open source that can be integrated with industry of any scale without have to worry about cost. Cost is calculated as design cost, development cost and maintenance cost. Development cost includes ETL cost and reporting cost. Further, the cost components are divided into activity list which includes design cost, extraction automation cost, transformation cost, loading cost, reporting cost and maintenance cost.

Cost Comparison –
- Design Cost
- Development Cost (ETL + Reporting License)
- Maintenance Cost

Activity Cost Estimates – Activity List for Cost Estimation:
- Design Cost
- Extraction Automation Cost
- Transformation Cost
- Loading Cost (All Above 3 are ETL Cost)
- Reporting Cost
- Maintenance Cost

To compare the cost, parametric estimation technique is used. Program evaluation and review technique (PERT) is used for comparison of cost with commercial tools versus proposed framework. Using PERT technique there are three scenarios for cost calculation – most likely, pessimistic and optimistic. Final cost is calculated using PERT formula which is \((O+P+4\times M)/6\) where \(O\) denotes optimistic, \(P\) denotes pessimistic and \(M\) denotes most likely.

Cost is evaluated for a DWH project having one year duration that includes development and operations support. Cost is evaluated for two scenarios a) Data warehouse with commercial ETL Tools and b) DWH system with proposed automated framework (without commercial tools). Parameters are taken for cost consideration including number of tool licenses, development time, operations time and report/retrieval users. For PERT evaluation; optimistic cost, pessimistic cost and most likely cost is calculated for DWH using commercial tools and DWH using proposed framework. Comparison chart is prepared as shown in Table 2 and observations are discussed.

Cost = \((O+P+4\times M)/6\)

Cost using two frameworks are calculated using PERT formula as given above.

So, by putting values –
- Total Cost using commercial tools = 
  \((1060240+4261200+4\times2118560)/6\)
  Estimated Cost of Project = $2299280
- Total Cost using automated framework = 
  \((962400+2628000+4\times1924800)/6\)
  Estimated Cost of Project = $1881600
- Total Cost Benefits using automated framework = $2299280 - $1881600 = $417680
Thus saving cost to build a DWH for an enterprise.

2) Time for Data Processing

The automation framework has been analyzed on the time parameter for data processing. The improved automation module should complete the automation in a highly efficient way and in time bound manner. Data processing mainly taking the area after the files arrived at transformation and loading sub process and is available at the fact tables with indexing on the tables. The resultant time has been analyzed number of files; number of records with three indexes is as shown in figure 5 and Time taken for processing (Using Traditional Approach) is captured and statistics are shown in figure 6.

Application of the framework is telecom DWH in which enormous number of data files are generated in the form of call data records.

<table>
<thead>
<tr>
<th>Number of License</th>
<th>With Commercial Tools (a)</th>
<th>With Automated Framework (b)</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Optimistic</td>
<td>Pessimistic</td>
</tr>
<tr>
<td>Number of License</td>
<td>1 ETL License</td>
<td>8 ETL License</td>
</tr>
<tr>
<td>Development Time (In Days)</td>
<td>20 Days</td>
<td>60 Days</td>
</tr>
<tr>
<td>Operations Time (365- Development Time) in Days</td>
<td>345 Days</td>
<td>305 Days</td>
</tr>
<tr>
<td>Total Cost</td>
<td>$1060240</td>
<td>$4261200</td>
</tr>
</tbody>
</table>

Table 2. Cost Estimation Using Pert Technique (Parametric Estimation)
3) Self-Healing/Revival Property of System
The automation framework has been evaluated on self-healing capabilities of the model. The data stream has been broken while transmitting for result. The auto revival property of system should ensure that the data available at source system should be available at the transformation and loading area for automation. It’s been observed that the error detection and correction mechanism is in place at source data process automation. Network communication has been cut for a while to check whether broken data stream has been successfully transmitted to next layer and redundancy has been handled or not. The data stream volume at source system and at transformation and loading area has been checked and verified. In this functional approach, self-healing property of proposed system is presented. In function run_sql_loader, technology mix technique with combination of external table, copy utility with parallel execution on partition exchange tables is first used for data processing. It take group of files presented at a time in an external table and load(s) it to the destination database.

The groups are referred as bunches and there may be multiple bunches processing at same time by making use of parallel thread technology. In case of issue in a particular bunch, whole bunch processing is suspended and group of files are moved automatically to different location for analysis and processing. For suspended bunch, different type of data processing is used in which row by row loading took place rather than group of files at one go. Benefit of using this approach is that, only in case of error in bunch processing – this technique is used and we can pinpoint the error records and get it fixed. Error handling and revival auto revival logic is incorporated.

4) Retrieval Time metrics
Statistics have been checked and retrieval time logs are analyzed. The function report_submission handles retrieval by identifying table partition of required data and locating indexes available on it. SQL query is optimized dynamically by adding partition and indexes as in-line hints. Optimized query is passed to the database for report generation.
The performance statistics are shown in figure 7 and figure 8. The report submission function runs every even minute. This total time taken to generate report 27 seconds from heavy DWH table containing billion of records (in Terabytes). The reporting is achieved without using existing reporting tools and saving cost on it.

VI. Conclusion

Automation framework proposed in this work has proved to be an effective solution for DWH system automation. Existing studies in the field of DWH system focused largely on extraction, transformation and loading while other parameter “reporting” should consider. DWH system for an organization has never been viewed as a single unified tool where reporting was also considered as its integral part. In this paper, DWH system process is provided as a complete unified tool covering all intermediate steps from data source to report generation. A minimized maintainability and manual intervention has been reported post implementation of framework. Framework resulted in an improved automation system which includes all major ETL processes.

Improved automation framework is evaluated on various parameters and significant improvement in all aspects is observed during result analysis phase. Encouraging results have been recorded on implementation of the automation framework in the context of cost, self-healing property, data processing time, maintainability and report retrieval time.

The automation framework not only automates the entire DWH system without using commercial tools, but also gives improved performance characteristics on all sub-systems of a DWH system. The framework can be used as a roadmap for any organization which is looking for setup its DWH system. Organizations can be benefitted by referring the framework and setting up of DWH with complete automation. Every aspect of setting up DWH is realized and worked upon to give comprehensive in-depth solution for a DWH. This work will be extended for scalability and fitment in the world of big data and analytics. The scope of the framework will be to expand in the area of big data and Hadoop like infrastructure to cope up with emerging data volumes of data driven industry.
